

Visualizing Geometric Morphisms

An application of the “Logic for Children”
project to Category Theory

(talk @ “Logic and Categories” workshop, UniLog 2018)

Logic / categories / toposes for children

(Very short version; for the long version see the resources for the “Logic for Children” workshop)

Many years ago...

Non-Standard Analysis

→ Johnstone’s “Topos Theory”

→ FAR too abstract for me

→ **I NEED A VERSION FOR CHILDREN OF THIS**

For Children: using “internal views” and

examples with finite objects that are easy to draw

Heyting Algebras that are subset of \mathbb{Z}^2 (paper)

Presheaves that can be drawn on a subset of \mathbb{Z}^2 (new)

Planar Heyting Algebras for Children

(↑ Very good paper! No prerequisites!

Lots of fun! Go read it!)

Most toposes have more than two truth-values and an intuitionistic logic.

The paper PHAfC shows how to visualize this (on ZHAs). It uses LR-coordinates and shows how the ' \rightarrow ' on ZHAs can be calculated quickly using a formula with four cases.

Planar Heyting Algebras for Children 2: Local Operators

The second paper in the series.

Sheaves *correspond* to local operators on HAs.

A local operator on a ZHA corresponds to slashing the ZHA by diagonal cuts and blurring the distinction between the truth-values in each region.

PHAfC doesn't mention categories.

PHAfC2 doesn't mention categories **yet**.

ZCategories

Choose a finite subset of \mathbb{Z}^2 .

(Optional step: rename its points.)

Use this set as the set of objects of a category.

Add a finite set of arrows.

This is a **ZCategory**.

The \mathbb{Z}^2 -coordinates tell how to draw it.

ZPresheaves and ZToposes

A ZPresheaf is a functor $F : \mathbf{A} \rightarrow \mathbf{Set}$,
where \mathbf{A} is a ZCategory.

(Obs: not $F : \mathbf{A}^{\text{op}} \rightarrow \mathbf{Set}$!)

A ZPresheaf F inherits its drawing instructions from \mathbf{A} .
("Positional notations")

$$\mathbf{A} = \left(\begin{array}{ccccc} 1 & & & & \\ & \searrow & & & \\ & & 2 & \longrightarrow & 3 \\ & \searrow & \downarrow & & \downarrow \\ & & 4 & \longrightarrow & 5 \end{array} \right) \quad F = \left(\begin{array}{ccccc} F_1 & & & & \\ & \searrow & & & \\ & & F_2 & \longrightarrow & F_3 \\ & \searrow & \downarrow & & \downarrow \\ & & F_4 & \longrightarrow & F_5 \end{array} \right)$$

A ZTopos is a category $\mathbf{Set}^{\mathbf{A}}$ where \mathbf{A} is a ZCategory.

Internal views

(Part 1: functions)

The internal view of the **function** $\sqrt{\cdot} : \mathbb{N} \rightarrow \mathbb{R}$ is:

(‘ \mapsto ’s take elements of a blob-set to another blob-set)

Internal views

(Part 2: functors)

Internal views of **functors** have blob-categories instead of blob-sets. Compare:

Internal views

(Part 3: omitting the blobs)

Internal views

(Part 4: adjunctions)

Left: generic adjunction $L \dashv R$

Middle: generic geometric morphism $f^* \dashv f_*$

Right: g.m. between toposes \mathbf{Set}^A and \mathbf{Set}^B

$$\begin{array}{ccc}
 LC & \longleftarrow & C \\
 \downarrow & \rightleftarrows & \downarrow \\
 D & \dashv & RD
 \end{array}$$

$$\mathbf{D} \begin{array}{c} \xleftarrow{L} \\ \xrightarrow{R} \end{array} \mathbf{C}$$

$$\begin{array}{ccc}
 f^*F & \longleftarrow & F \\
 \downarrow & \rightleftarrows & \downarrow \\
 G & \dashv & f_*G
 \end{array}$$

$$\mathcal{E} \begin{array}{c} \xleftarrow{f^*} \\ \xrightarrow{f_*} \end{array} \mathcal{F}$$

$$\begin{array}{ccc}
 f^*F & \longleftarrow & F \\
 \downarrow & \rightleftarrows & \downarrow \\
 G & \dashv & f_*G
 \end{array}$$

$$\mathbf{Set}^A \begin{array}{c} \xleftarrow{f^*} \\ \xrightarrow{f_*} \end{array} \mathbf{Set}^B$$

$$\mathbf{A} \xrightarrow{f} \mathbf{B}$$

Working in two languages in parallel

Ideas: do things “for children” and “for adults”
in **parallel**, find ways to *transfer knowledge*
between the two approaches...

The diagrams for the general case and for a particular case
have the same shape!!!

Working in two universes in parallel

In Non-Standard Analysis we have *transfer theorems*

$$\left(\begin{array}{c} \text{Standard} \\ \text{universe} \end{array} \right) \begin{array}{c} \longleftarrow \\ \longrightarrow \end{array} \left(\begin{array}{c} \text{Non-Standard} \\ \text{universe} \\ \text{(ultrapower)} \end{array} \right)$$

Our first geometric morphism

(for children; inclusion, sheaf)

$$\begin{array}{ccc}
 f^*F & \longleftarrow & F \\
 \downarrow & \rightleftharpoons & \downarrow \\
 G & \longrightarrow & f_*G \\
 \mathcal{F} & \xrightleftharpoons[f_*]{f^*} & \mathcal{E}
 \end{array}$$

(for adults)

A factorization

Elephant = Bible

Section A4: Geometric Morphisms

Each ‘ \longrightarrow ’ below is a g.m. (an adjunction)

Any g.m. factors as a surjection followed by an inclusion.

Any inclusion factors as a dense g.m.

followed by a closed g.m. .

$$\begin{array}{ccccc}
 \mathcal{A} & \xrightarrow{\text{any}} & & & \mathcal{D} \\
 \mathcal{A} & \xrightarrow{\text{surjection}} & \mathcal{B} & \xrightarrow{\text{inclusion}} & \mathcal{D} \\
 & & \mathcal{B} & \xrightarrow{\text{dense}} & \mathcal{C} & \xrightarrow{\text{close}} & \mathcal{D}
 \end{array}$$

The Elephant *constructs* the toposes \mathcal{B} , \mathcal{C} and the maps.

A factorization: version using ZPresheaves

This would be a nicer theorem — that if we start with ZToposes $\mathbf{Set}^{\mathbf{A}}$ and $\mathbf{Set}^{\mathbf{D}}$ the factorization can be through ZToposes...

$$\begin{array}{ccccc}
 \mathbf{Set}^{\mathbf{A}} & \xrightarrow{\text{any}} & & & \mathbf{Set}^{\mathbf{D}} \\
 \parallel & & & & \parallel \\
 \mathbf{Set}^{\mathbf{A}} & \xrightarrow{\text{surjection}} & \mathcal{B} & \xrightarrow{\text{inclusion}} & \mathbf{Set}^{\mathbf{D}} \\
 & & \parallel & & \parallel \\
 & & \mathbf{Set}^{\mathbf{B}} & \xrightarrow{\text{dense}} & \mathcal{C} & \xrightarrow{\text{closed}} & \mathbf{Set}^{\mathbf{D}} \\
 & & & & \parallel & & \\
 & & & & \mathbf{Set}^{\mathbf{C}} & &
 \end{array}$$

That factorization, for children

We start with a particular case, with a factorization that only has ZToposes, and we use it to understand how the Elephant defines sujection, inclusion, etc...
 (s is not an inclusion, i is not a surjection, and so on)

$$\begin{array}{ccccc}
 & F & & G & & H & & I \\
 \mathbf{Set}^A & \xrightarrow{g \text{ (any)}} & & & & & & \mathbf{Set}^D \\
 \parallel & & & & & & & \parallel \\
 \mathbf{Set}^A & \xrightarrow{s \text{ (surjection)}} & \mathbf{Set}^B & \xrightarrow{i \text{ (inclusion)}} & & & & \mathbf{Set}^D \\
 & & \parallel & & & & & \parallel \\
 & & \mathbf{Set}^B & \xrightarrow{d \text{ (dense)}} & \mathbf{Set}^C & \xrightarrow{c \text{ (closed)}} & & \mathbf{Set}^D
 \end{array}$$

The surjection-inclusion factorization for children

$$\begin{array}{ccc}
 g^*I & \longleftarrow & I \\
 \downarrow & & \downarrow \\
 F & \xrightarrow{\quad} & g_*F \\
 \text{Set}^A & \xrightarrow{g \text{ (any)}} & \text{Set}^D
 \end{array}
 \quad \longleftrightarrow \quad
 \begin{array}{ccc}
 s^*G & \longleftarrow & G \\
 \downarrow & & \downarrow \\
 F & \xrightarrow{\quad} & s_*F \\
 \text{Set}^A & \xrightarrow{s \text{ (surjection)}} & \text{Set}^B
 \end{array}
 \quad \longleftrightarrow \quad
 \begin{array}{ccc}
 G & \xrightarrow{\eta^G \text{ (monic)}} & i^*i_*G \\
 \downarrow & & \downarrow \\
 G & \xrightarrow{\epsilon^G \text{ (iso)}} & G \\
 \text{Set}^B & \xrightarrow{i \text{ (inclusion)}} & \text{Set}^D
 \end{array}$$

The dense-closed factorization for children

$$\begin{array}{ccc}
 i^*i_*G & i^*I & \longleftarrow I \\
 \downarrow \scriptstyle \begin{smallmatrix} \epsilon G \\ \text{(iso)} \end{smallmatrix} & \downarrow & \downarrow \\
 G & G & i_*G \\
 \text{Set}^B & \xrightarrow{i \text{ (inclusion)}} & \text{Set}^D
 \end{array}
 \quad \Leftrightarrow$$

$$\begin{array}{ccc}
 d^*H & \longleftarrow H & K \\
 \downarrow & \Leftrightarrow & \downarrow \scriptstyle \begin{smallmatrix} \eta K \\ \text{(monic)} \end{smallmatrix} \\
 G & \longrightarrow d_*G & d_*d^*K \\
 \text{Set}^B & \xrightarrow{d \text{ (dense)}} & \text{Set}^C
 \end{array}
 \quad
 \begin{array}{ccc}
 c^*I & \longleftarrow I & \\
 \downarrow & \Leftrightarrow & \downarrow \\
 H & \longrightarrow c_*H & \\
 \text{Set}^C & \xrightarrow{c \text{ (closed)}} & \text{Set}^D
 \end{array}$$

(K is a constant ZPresheaf in Set^C)

According to the Elephant...

A4.2.7, 4.2.10:
to build \mathcal{B} we need
comonads and
coalgebras

A4.5.9, A4.5.20:
 $\mathcal{C} = \text{sh}_{\neg\neg}(\text{Set}^{\mathcal{D}})$
(can't be!)

$$\begin{array}{ccc}
 \text{Set}^{\mathcal{A}} & \xrightarrow{a \text{ (any)}} & \text{Set}^{\mathcal{D}} \\
 \parallel & & \parallel \\
 \text{Set}^{\mathcal{A}} & \xrightarrow{s \text{ (surjection)}} \mathcal{B} & \xrightarrow{i \text{ (inclusion)}} \text{Set}^{\mathcal{D}} \\
 & \parallel & \parallel \\
 & (\text{Set}^{\mathcal{B}})_{\mathcal{G}} & \\
 & \parallel & \\
 \text{Set}^{\mathcal{B}} & \xrightarrow{d \text{ (dense)}} \mathcal{C} & \xrightarrow{c \text{ (closed)}} \text{Set}^{\mathcal{D}} \\
 & \parallel & \parallel \\
 & \text{sh}_{\neg\neg}(\text{Set}^{\mathcal{D}}) \text{ (???) } & \\
 & \parallel & \\
 & \text{Set}^{\mathcal{C}} &
 \end{array}$$

Another strategy

Start with a functor $g : \mathbf{A} \rightarrow \mathbf{D}$.

It induces a geometric morphism $g^* \dashv g_*$.

g^* is trivial to build.

g_* can be found by guess-and-test.

(or by Kan extensions)

The functor g can:

collapse objects, $(1 \ 2) \rightarrow (1)$

create objects, $() \rightarrow (3)$

collapse arrows, $(4 \rightrightarrows 5) \rightarrow (4 \rightarrow 5)$

create arrows, $(6 \ 7) \rightarrow (6 \rightarrow 7)$

Try to factor it. Example: if g just collapses objects...

Another strategy

The functor g can do several **things**:

collapse objects, $(1 \ 2) \rightarrow (1)$

create objects, $() \rightarrow (3)$

collapse arrows, $(4 \rightrightarrows 5) \rightarrow (4 \rightarrow 5)$

create arrows, $(6 \ 7) \rightarrow (6 \rightarrow 7)$

refine the order, $(2 \rightarrow 4) \rightarrow (1 \rightarrow 2 \rightarrow 3 \rightarrow 4 \rightarrow 5) \dots$

Try to factor it.

Example: if g just **collapses** objects,

then it factor as $s = g$ (surj. part), $i = \text{id}$ (inclusion part)...

The factorization filters the *things* that the functor can do,

collapsing objects go to the surjective part.

Another strategy

Choose a functor

$$f : \mathbf{A} \rightarrow \mathbf{B}$$

that does all **things**.

Factorize it.

\mathcal{B} and \mathcal{C} will

be non-trivial.

They tell us how

\mathcal{B} and \mathcal{C} will be

modulo

isomorphism.

$$\begin{array}{ccccc}
 \mathbf{Set}^{\mathbf{A}} & \xrightarrow{a \text{ (any)}} & & & \mathbf{Set}^{\mathbf{D}} \\
 \parallel & & & & \parallel \\
 \mathbf{Set}^{\mathbf{A}} & \xrightarrow{s \text{ (surjection)}} & \mathcal{B} & \xrightarrow{i \text{ (inclusion)}} & \mathbf{Set}^{\mathbf{D}} \\
 & & \parallel & & \parallel \\
 & & (\mathbf{Set}^{\mathbf{B}})_{\mathbf{G}} & & \\
 & & \parallel & & \\
 & & \mathbf{Set}^{\mathbf{B}} & \xrightarrow{d \text{ (dense)}} & \mathcal{C} \xrightarrow{c \text{ (closed)}} & \mathbf{Set}^{\mathbf{D}} \\
 & & & & \parallel \\
 & & & & \text{sh}_{\neg\neg}(\mathbf{Set}^{\mathbf{D}}) \text{ (???)} \\
 & & & & \parallel \\
 & & & & \mathbf{Set}^{\mathbf{C}}
 \end{array}$$
